

Whats REAL — Master Project & Idea Document

Purpose: This is the master copy of the Whats REAL concept (product + platform) and can be updated over time as new thoughts are added.

Core philosophy: *Truth comes from people who were really there.* Location becomes the trust layer, and AI protects authenticity without replacing human voice.

1. Vision & Ideology

Whats REAL is a location-verified intelligence platform. Users ask hyperlocal questions tagged to real places using Google Places. Only people who have actually been in that location (within a 50–100m radius) are eligible to respond. This drives authenticity, reduces spam, and increases trust.

The app prioritizes simple UX (Quora-like reading + asking) with powerful trust mechanics under the hood.

2. Core User Experience

Ask: Post a question as text or a ≤10-second video, tag a location (Google Places) and optionally set response types (comment/video/rating).

Verify: The system selects eligible responders based on location history and a minimum radius (50–100m).

Respond: Responders can reply via text, ≤10-second video, and/or rating (if enabled).

Notify: If the target user is active → in-app; otherwise → push notification with the question context.

System Diagram:

3. Key Requirements (Consolidated)

Area	Decision
Authentication	Easy sign-up; start with Email/Password, add social login later
Profiles	Mandatory profile with basic demographics + social status

Location tagging	Google Places API
Radius	50–100 meters
Media	≤10-second recordings using Apple SDKs (AVFoundation/AVKit)
Backend	Firebase (Auth, Firestore, Storage, FCM) as cost-effective BaaS
Sharing	Instagram, Facebook, X, Quora

4. AI Strategy — AI as the Referee

AI should not answer questions. AI's role is to protect the platform by analyzing authenticity and abuse patterns.

4.1 Authenticity Confidence

Every content item (text/video/audio) receives an **Authenticity Confidence** rating: High / Mixed / Low. The app avoids direct accusations and instead communicates confidence transparently.

4.2 What AI Analyzes (Signals)

Text signals: unnatural consistency, generic phrasing, repetition, speed-of-response anomalies, copy/paste patterns.

Audio/video signals: synthetic voice markers, lip-sync artifacts, missing ambient noise, unrealistic clarity vs environment.

Context signals: mismatch with time/place, lack of situational detail, suspicious multi-location activity.

4.3 Outcome

Low-confidence content is **de-prioritized** and can be escalated for review if repeated. High-confidence content improves user trust score.

5. New Platform Idea — Trust as a Service

Beyond the Whats REAL app, the authenticity engine becomes a service: **review the reviewers** and provide authenticity scoring to other apps.

Goal: Prevent fake reviews, scams, misinformation, and illegal activity by providing a genuine-review trust layer for any platform that uses user-generated content.

Platform Diagram:

5.1 Service Outputs (for Partner Apps)

- Authenticity score (0–100) + confidence band
- Scam risk score
- Behavior flags (burst activity, copy patterns, bot-like signals)
- Optional: location verification signal (if partner supports it)

6. Reputation & Scoring (User Trust Graph)

Users build trust over time based on: verified-location responses, authenticity confidence averages, community ratings, and consistency. High-trust users get more visibility; low-trust users are throttled.

Key point: Trust affects ranking, not basic access. This reduces false-positive harm while still protecting users.

7. Technical Architecture (MVP)

iOS: Swift + SwiftUI (MVVM + Service layer), CoreLocation, AVFoundation/AVKit, UIActivityViewController for sharing.

Firebase: Auth, Firestore, Storage (video), Cloud Messaging (push).

Reusable components: Buttons, input fields, location picker, video recorder, feed cells. Build as modular UI and services for future reuse.

8. Compliance, Safety & Privacy

- Request permissions at time-of-use with clear explanations.
- Prefer on-device checks where possible.
- Store only minimal location signals needed for eligibility.
- Provide user controls (opt-out, delete, visibility settings).

9. Market Positioning (Fresh Usage)

Whats REAL creates a new category: **Location-Verified Intelligence**. It becomes valuable as AI-generated noise increases. The Trust■as■a■Service layer extends this into a scalable B2B business.

10. Next Steps (Recommended)

1) Implement MVP flow: Auth → Profile → Ask → Verify → Notify → Respond. 2) Add authenticity scoring (v1) + reputation model. 3) Launch in one city (invite beta) and measure response time + retention. 4) Create partner SDK/API spec for Trust■as■a■Service and onboard first pilots.
